

## STEP Support Programme

### Hints and partial solutions for Assignment 25

#### Warm-up

- 1 (i) (a) The integral becomes:

$$\begin{aligned} \int \frac{u+2}{u} \times 1 \, du &= \int 1 + \frac{2}{u} \, du \\ &= u + 2 \ln |u| + c \\ &= x - 2 + 2 \ln |x - 2| + c. \end{aligned}$$

You can, if you wish, combine the “ $-2$ ” with the constant of integration to get a final answer of  $x + 2 \ln |x - 2| + k$ . This is not a necessary step, but does look a little nicer.

- (b) Here we have:

$$\begin{aligned} \int \frac{3(u^2 - 1)}{x} \times x \, du &= 3 \int (u^2 - 1) \, du \\ &= 3 \left( \frac{1}{3} u^3 - u \right) + c \\ &= u^3 - 3u + c \\ &= (2x + 1)^{\frac{3}{2}} - 3(2x + 1)^{\frac{1}{2}} + c \end{aligned}$$

The final answer could also be written as  $2(x - 1)\sqrt{2x + 1} + c$  (by factorising out  $(2x + 1)^{\frac{1}{2}}$ ).

- (ii) In the case the integral becomes:

$$\begin{aligned} \int_0^{\frac{1}{6}\pi} \frac{1}{\sqrt{4 - 4\sin^2 \theta}} \times 2 \cos \theta \, d\theta &= \int_0^{\frac{1}{6}\pi} \frac{1}{2\cos \theta} \times 2\cos \theta \, d\theta \\ &= \int_0^{\frac{1}{6}\pi} 1 \, d\theta \\ &= \left[ \theta \right]_0^{\frac{1}{6}\pi} \\ &= \frac{1}{6}\pi \end{aligned}$$

## Preparation

- 2 (i) Since you are given  $A$  and  $B$  in the question you should stick with these variables (rather than using  $a$  and  $b$ ). We have:

$$\begin{aligned} \tan(A - B) &= \frac{\sin(A - B)}{\cos(A - B)} \\ &= \frac{\sin A \cos B - \sin B \cos A}{\cos A \cos B + \sin A \sin B} \\ &= \frac{\frac{\sin A \cos B}{\cos A \cos B} - \frac{\sin B \cos A}{\cos A \cos B}}{\frac{\cos A \cos B}{\cos A \cos B} + \frac{\sin A \sin B}{\cos A \cos B}} \\ &= \frac{\tan A - \tan B}{1 + \tan A \tan B} \end{aligned}$$

- (ii) One approach is:

$$\begin{aligned} \ln\left(1 + \frac{\frac{1}{2} - x}{\frac{1}{2} + x}\right) &= \ln\left(\frac{\frac{1}{2} + x + \frac{1}{2} - x}{\frac{1}{2} + x}\right) \\ &= \ln\left(\frac{1}{\frac{1}{2} + x}\right) \\ &= \ln 1 - \ln\left(\frac{1}{2} + x\right) \\ &= -\ln\left(\frac{1}{2} + x\right) \end{aligned}$$

- (iii) Dividing throughout by  $\cos^2 \theta$  gives  $\tan^2 \theta + 1 \equiv \sec^2 \theta$ .

This is a result worth “knowing by heart”, or at least being able to derive fairly quickly.

- (iv) The quotient rule (using a prime to denote differentiation)

$$\left(\frac{u}{v}\right)' = \frac{u'v - v'u}{v^2}$$

follows immediately from the product rule applied to  $uv^{-1}$  using the chain rule to differentiate  $v^{-1}$  (which gives  $-v^{-2}v'$ ).

Using this we have:

$$\begin{aligned} \frac{d}{d\theta} \left(\frac{\sin \theta}{\cos \theta}\right) &= \frac{\cos \theta \times \cos \theta - (-\sin \theta) \times \sin \theta}{\cos^2 \theta} \\ &= \frac{1}{\cos^2 \theta} \\ &= \sec^2 \theta. \end{aligned}$$

Another result which is good to “know by heart”!

(v) One approach is:

$$\begin{aligned} \frac{1 + \sin 2\alpha}{1 + \cos 2\alpha} &= \frac{\cos^2 \alpha + \sin^2 \alpha + 2 \sin \alpha \cos \alpha}{\cos^2 \alpha + \sin^2 \alpha + \cos^2 \alpha - \sin^2 \alpha} \\ &= \frac{(\sin \alpha + \cos \alpha)^2}{2 \cos^2 \alpha} \\ &= \frac{1}{2} \left( \frac{\sin \alpha + \cos \alpha}{\cos \alpha} \right)^2 \\ &= \frac{1}{2} (\tan \alpha + 1)^2 \end{aligned}$$

(vi) The answer is given, so you do need to show some working:

$$\begin{aligned} \int_0^{84} \frac{x^2}{x^2 + (84 - x)^2} dx &= \int_{84}^0 \frac{(84 - u)^2}{(84 - u)^2 + u^2} \times -1 du \\ &= -1 \times - \int_0^{84} \frac{(84 - u)^2}{u^2 + (84 - u)^2} du \\ &= \int_0^{84} \frac{(84 - x)^2}{x^2 + (84 - x)^2} dx \end{aligned}$$

where the last step involves a substitution of  $u = x$ .

We then have:

$$\begin{aligned} I + I &= \int_0^{84} \frac{x^2}{x^2 + (84 - x)^2} dx + \int_0^{84} \frac{(84 - x)^2}{x^2 + (84 - x)^2} dx \\ &= \int_0^{84} \frac{x^2 + (84 - x)^2}{x^2 + (84 - x)^2} dx \\ &= \int_0^{84} 1 dx = 84 \end{aligned}$$

so  $2I = 84$  and hence  $I = 42$ .

## The STEP question (1994 STEP I Q8)

3 Using the given substitution we have:

$$\begin{aligned}
 I &= \int_0^{\frac{1}{4}\pi} \ln(1 + \tan \theta) \, d\theta = \int_{\frac{1}{4}\pi}^0 \ln(1 + \tan(\frac{1}{4}\pi - \phi)) \times -1 \, d\phi \\
 &= \int_0^{\frac{1}{4}\pi} \ln\left(1 + \frac{1 - \tan \phi}{1 + \tan \phi}\right) \, d\phi && \text{using } \tan(\frac{1}{4}\pi) = 1 \\
 &= \int_0^{\frac{1}{4}\pi} \ln\left(\frac{1 + \cancel{\tan \phi} + 1 - \cancel{\tan \phi}}{1 + \tan \phi}\right) \, d\phi \\
 &= \int_0^{\frac{1}{4}\pi} (\ln 2 - \ln(1 + \tan \phi)) \, d\phi \\
 &= \int_0^{\frac{1}{4}\pi} \ln 2 \, d\phi - I \\
 &= \left[\phi \ln 2\right]_0^{\frac{1}{4}\pi} - I \\
 &= \frac{1}{4}\pi \ln 2 - I.
 \end{aligned}$$

Don't forget that  $\ln 2$  is a constant so when we integrate we get  $\phi \times \ln 2$ . We now have  $I = \frac{1}{4}\pi \ln 2 - I$  and so we have  $I = \frac{1}{8}\pi \ln 2$ .

(i) Looking at the limits, and thinking that we would like something that looks a little like the first integral, try  $x = \tan \theta$ .

$$\begin{aligned}
 \int_0^1 \frac{\ln(1+x)}{1+x^2} \, dx &= \int_0^{\frac{1}{4}\pi} \frac{\ln(1+\tan \theta)}{1+\cancel{\tan^2 \theta}} \times \cancel{\sec^2 \theta} \, d\theta \\
 &= \frac{1}{8}\pi \ln 2.
 \end{aligned}$$

(ii) You can get a hint of what to use by looking at the upper limit of the integral. Starting with  $x = 2u$  gives:

$$\begin{aligned}
 \int_0^{\frac{1}{2}\pi} \ln\left(\frac{1+\sin x}{1+\cos x}\right) \, dx &= \int_0^{\frac{1}{4}\pi} \ln\left(\frac{1+\sin 2u}{1+\cos 2u}\right) \times 2 \, du \\
 &= \int_0^{\frac{1}{4}\pi} \ln\left(\frac{1}{2}(1+\tan u)^2\right) \times 2 \, du && \text{using } \mathbf{2(v)} \\
 &= 2 \int_0^{\frac{1}{4}\pi} \left[\ln\left(\frac{1}{2}\right) + \ln(1+\tan u)^2\right] \, du \\
 &= 2 \int_0^{\frac{1}{4}\pi} \ln\left(\frac{1}{2}\right) \, du + 4 \int_0^{\frac{1}{4}\pi} \ln(1+\tan u) \, du \\
 &= 2 \left[u \times \ln\left(\frac{1}{2}\right)\right]_0^{\frac{1}{4}\pi} + 4 \times \frac{1}{8}\pi \ln 2 \\
 &= 2 \times \frac{1}{4}\pi \times (-\ln 2) + \frac{1}{2}\pi \ln 2 = 0
 \end{aligned}$$

If you hadn't done the preparation questions first, you will have had to do some more lines of working to get to the expression in  $\tan u$ . However, knowing what sort of expression you are aiming for is a big help, and using the limits to suggest a suitable substitution is usually a good idea.

Other methods are also possible!

## Warm down

- 4 (i) Use  $t = a - x$  to give:

$$\begin{aligned} I &= \int_0^a \frac{f(x)}{f(x) + f(a-x)} dx = \int_a^0 \frac{f(a-t)}{f(a-t) + f(t)} \times -1 dt \\ &= \int_0^a \frac{f(a-t)}{f(a-t) + f(t)} dt \\ &= \int_0^a \frac{f(a-x)}{f(a-x) + f(x)} dx \end{aligned}$$

Then we have  $2I = \int_0^a 1 dx = a$  and hence  $I = \frac{1}{2}a$ .

For the last part, first note that  $\cos x + \sin x \neq 0$  in the range  $0 \leq x \leq \frac{1}{2}\pi$ .

We can use  $\sin x = \cos(\frac{1}{2}\pi - x)$  to get:

$$\int_0^{\frac{1}{2}\pi} \frac{\cos x}{\cos x + \cos(\frac{1}{2}\pi - x)} dx$$

which is now in the same form as the previous integral, so this integral is equal to  $\frac{1}{2}a = \frac{1}{4}\pi$ .

- (ii) The result  $\int \frac{f'(x)}{f(x)} dx = \ln|f(x)| + c$  is well worth memorising!

(a) Here  $f(x) = \sin x$ , so the integral is  $\left[ \ln|\sin(x)| \right]_{\frac{\pi}{4}}^{\frac{\pi}{2}} = \ln 1 - \ln \frac{1}{\sqrt{2}} = \frac{1}{2} \ln 2$ .

(b) Writing the integral in the form  $\int \frac{1}{x \ln x} dx$  gives the result

$$\int \frac{1}{x \ln x} dx = \ln|\ln x| + c.$$

(c)  $S + T = x + c_1$  and  $S - T = \ln(\cos x + \sin x) + c_2$  (using (†) for the second of these integrals). You can then solve simultaneous equations to give:

$$\begin{aligned} S &= \frac{1}{2}x + \frac{1}{2} \ln(\cos x + \sin x) + k_1 \\ T &= \frac{1}{2}x - \frac{1}{2} \ln(\cos x + \sin x) + k_2. \end{aligned}$$
